

Cypher is the declarative query language for Neo4j, the world’s leading graph database.

Key principles and capabilities of Cypher are as follows:

- Cypher matches patterns of nodes and relationships in the graph, to extract information or modify the data.
- Cypher has the concept of variables which denote named, bound elements and parameters.
- Cypher can create, update, and remove nodes, relationships, labels, and properties.
- Cypher manages indexes and constraints.

You can try Cypher snippets live in the Neo4j Console at console.neo4j.org or read the full Cypher documentation in the [Neo4j Developer Manual](#). For live graph models using Cypher check out [GraphGist](#).

The Cypher Refcard is also [available in PDF format](#).

Note: {value} denotes either literals or maps, used for ad hoc Cypher queries. The usage of parameters is recommended in applications, and are denoted by \$value. Neo4j properties can be strings, numbers, booleans or arrays thereof. Cypher also supports maps and lists.

Syntax

Read Query Structure
<pre>[MATCH WHERE] [OPTIONAL MATCH WHERE] [WITH [ORDER BY] [SKIP] [LIMIT]] RETURN [ORDER BY] [SKIP] [LIMIT]</pre>

MATCH
<pre>MATCH (n:Person)-[:KNOWS]->(m:Person) WHERE n.name = 'Alice'</pre> Node patterns can contain labels and properties.
<pre>MATCH (n)-->(m)</pre> Any pattern can be used in MATCH.
<pre>MATCH (n {name: 'Alice'})-->(m)</pre> Patterns with node properties.
<pre>MATCH p = (n)-->(m)</pre> Assign a path to p.
<pre>OPTIONAL MATCH (n)-[r]->(m)</pre> Optional pattern: nulls will be used for missing parts.

WHERE
<pre>WHERE n.property <> \$value</pre> Use a predicate to filter. Note that WHERE is always part of a MATCH, OPTIONAL MATCH, WITH or START clause. Putting it after a different clause in a query will alter what it does.

Write-Only Query Structure
<pre>(CREATE [UNIQUE] MERGE)* [SET DELETE REMOVE FOREACH]* [RETURN [ORDER BY] [SKIP] [LIMIT]]</pre>

Read-Write Query Structure
<pre>[MATCH WHERE] [OPTIONAL MATCH WHERE] [WITH [ORDER BY] [SKIP] [LIMIT]] (CREATE [UNIQUE] {vbar} MERGE)* [SET{vbar}DELETE{vbar}REMOVE{vbar}FOREACH]* [RETURN [ORDER BY] [SKIP] [LIMIT]]</pre>

CREATE
<pre>CREATE (n {name: \$value})</pre> Create a node with the given properties.
<pre>CREATE (n \$map)</pre> Create a node with the given properties.
<pre>UNWIND \$listOfMaps AS properties CREATE (n) SET n = properties</pre> Create nodes with the given properties.
<pre>CREATE (n)-[:KNOWS]->(m)</pre> Create a relationship with the given type and direction; bind a variable to it.
<pre>CREATE (n)-[:LOVES {since: \$value}]->(m)</pre> Create a relationship with the given type, direction, and properties.

SET
<pre>SET n.property1 = \$value1, n.property2 = \$value2</pre> Update or create a property.
<pre>SET n = \$map</pre> Set all properties. This will remove any existing properties.
<pre>SET n += \$map</pre> Add and update properties, while keeping existing ones.
<pre>SET n:Person</pre> Adds a label Person to a node.

Import
<pre>LOAD CSV FROM 'https://neo4j.com/docs/cypher- refcard/3.2/csv/artists.csv' AS line CREATE (:Artist {name: line[1], year: toInt(line[2])})</pre> Load data from a CSV file and create nodes.
<pre>LOAD CSV WITH HEADERS FROM 'https://neo4j.com/docs/cypher-refcard/3.2/csv/artists- with-headers.csv' AS line CREATE (:Artist {name: line.Name, year: toInt(line.Year)})</pre> Load CSV data which has headers.
<pre>LOAD CSV FROM 'https://neo4j.com/docs/cypher-refcard/3.2/csv/artists- fieldterminator.csv' AS line FIELDTERMINATOR ';' CREATE (:Artist {name: line[1], year: toInt(line[2])})</pre> Use a different field terminator, not the default which is a comma (with no whitespace around it).

RETURN
<pre>RETURN *</pre> Return the value of all variables.
<pre>RETURN n AS columnName</pre> Use alias for result column name.
<pre>RETURN DISTINCT n</pre> Return unique rows.
<pre>ORDER BY n.property</pre> Sort the result.
<pre>ORDER BY n.property DESC</pre> Sort the result in descending order.
<pre>SKIP \$skipNumber</pre> Skip a number of results.
<pre>LIMIT \$limitNumber</pre> Limit the number of results.
<pre>SKIP \$skipNumber LIMIT \$limitNumber</pre> Skip results at the top and limit the number of results.
<pre>RETURN count(*)</pre> The number of matching rows. See Aggregating Functions for more.

WITH
<pre>MATCH (user)-[:FRIEND]-(friend) WHERE user.name = \$name WITH user, count(friend) AS friends WHERE friends > 10 RETURN user</pre> The WITH syntax is similar to RETURN. It separates query parts explicitly, allowing you to declare which variables to carry over to the next part.
<pre>MATCH (user)-[:FRIEND]-(friend) WITH user, count(friend) AS friends ORDER BY friends DESC SKIP 1 LIMIT 3 RETURN user</pre> ORDER BY, SKIP, and LIMIT can also be used with WITH.

UNION
<pre>MATCH (a)-[:KNOWS]->(b) RETURN b.name UNION MATCH (a)-[:LOVES]->(b) RETURN b.name</pre> Returns the distinct union of all query results. Result column types and names have to match.
<pre>MATCH (a)-[:KNOWS]->(b) RETURN b.name UNION ALL MATCH (a)-[:LOVES]->(b) RETURN b.name</pre> Returns the union of all query results, including duplicated rows.

MERGE
<pre>MERGE (n:Person {name: \$value}) ON CREATE SET n.created = timestamp() ON MATCH SET n.counter = coalesce(n.counter, 0) + 1, n.accessTime = timestamp()</pre> Match a pattern or create it if it does not exist. Use ON CREATE and ON MATCH for conditional updates.
<pre>MATCH (a:Person {name: \$value1}), (b:Person {name: \$value2}) MERGE (a)-[r:LOVES]->(b)</pre> MERGE finds or creates a relationship between the nodes.
<pre>MATCH (a:Person {name: \$value1}) MERGE (a)-[r:KNOWS]->(b:Person {name: \$value3})</pre> MERGE finds or creates subgraphs attached to the node.

DELETE
<pre>DELETE n, r</pre> Delete a node and a relationship.
<pre>DETACH DELETE n</pre> Delete a node and all relationships connected to it.
<pre>MATCH (n) DETACH DELETE n</pre> Delete all nodes and relationships from the database.

REMOVE
<pre>REMOVE n:Person</pre> Remove a label from n.
<pre>REMOVE n.property</pre> Remove a property.

FOREACH
<pre>FOREACH (r IN relationships(path) SET r.marked = true)</pre> Execute a mutating operation for each relationship in a path.
<pre>FOREACH (value IN coll CREATE (:Person {name: value}))</pre> Execute a mutating operation for each element in a list.

CALL
<pre>CALL db.labels() YIELD label</pre> This shows a standalone call to the built-in procedure db.labels to list all labels used in the database. Note that required procedure arguments are given explicitly in brackets after the procedure name.
<pre>CALL java.stored.procedureWithArgs</pre> Standalone calls may omit YIELD and also provide arguments implicitly via statement parameters, e.g. a standalone call requiring one argument input may be run by passing the parameter map {input: 'foo'}.
<pre>CALL db.labels() YIELD label RETURN count(label) AS count</pre> Calls the built-in procedure db.labels inside a larger query to count all labels used in the database. Calls inside a larger query always requires passing arguments and naming results explicitly with YIELD.

String matching
STARTS WITH, ENDS WITH, CONTAINS

null
<ul style="list-style-type: none">• null is used to represent missing/undefined values.• null is not equal to null. Not knowing two values does not imply that they are the same value. So the expression null = null yields null and not true. To check if an expression is null, use IS NULL.• Arithmetic expressions, comparisons and function calls (except coalesce) will return null if any argument is null.• An attempt to access a missing element in a list or a property that doesn't exist yields null.• In OPTIONAL MATCH clauses, nulls will be used for missing parts of the pattern.

Patterns
<pre>(n:Person)</pre> Node with Person label.
<pre>(n:Person:Swedish)</pre> Node with both Person and Swedish labels.
<pre>(n:Person {name: \$value})</pre> Node with the declared properties.
<pre>()-[r {name: \$value}]-()</pre> Matches relationships with the declared properties.
<pre>(n)-->(m)</pre> Relationship from n to m.
<pre>(n)--(m)</pre> Relationship in any direction between n and m.
<pre>(n:Person)-->(m)</pre> Node n labeled Person with relationship to m.
<pre>(m)-[:KNOWS]-(n)</pre> Relationship of type KNOWS from n to m.
<pre>(n)-[:KNOWS :LOVES]->(m)</pre> Relationship of type KNOWS or of type LOVES from n to m.
<pre>(n)-[r]->(m)</pre> Bind the relationship to variable r.
<pre>(n)-[*1..5]->(m)</pre> Variable length path of between 1 and 5 relationships from n to m.
<pre>(n)-[*]->(m)</pre> Variable length path of any number of relationships from n to m. (See Performance section.)
<pre>(n)-[:KNOWS]->(m {property: \$value})</pre> A relationship of type KNOWS from a node n to a node m with the declared property.
<pre>shortestPath((n1:Person)-[*..6]-(n2:Person))</pre> Find a single shortest path.
<pre>allShortestPaths((n1:Person)-[*..6]->(n2:Person))</pre> Find all shortest paths.
<pre>size((n)-->()->())</pre> Count the paths matching the pattern.

Lists
<pre>['a', 'b', 'c'] AS list</pre> Literal lists are declared in square brackets.
<pre>size(\$list) AS len, \$list[0] AS value</pre> Lists can be passed in as parameters.
<pre>range(\$firstNum, \$lastNum, \$step) AS list</pre> range() creates a list of numbers (step is optional), other functions returning lists are: labels(), nodes(), relationships(), filter(), extract().
<pre>MATCH (a)-[r:KNOWS*]->() RETURN r AS rels</pre> Relationship variables of a variable length path contain a list of relationships.
<pre>RETURN matchedNode.list[0] AS value, size(matchedNode.list) AS len</pre> Properties can be lists of strings, numbers or booleans.

<pre>list[\$idx] AS value, list[\$startIdx..\$endIdx] AS slice</pre> List elements can be accessed with idx subscripts in square brackets. Invalid indexes return null. Slices can be retrieved with intervals from start_idx to end_idx, each of which can be omitted or negative. Out of range elements are ignored.
--

<pre>UNWIND \$names AS name MATCH (n {name: name}) RETURN avg(n.age)</pre> With UNWIND, any list can be transformed back into individual rows. The example matches all names from a list of names.
<pre>MATCH (a) RETURN [(a)-->(b) WHERE b.name = 'Bob' b.age]</pre> Pattern comprehensions may be used to do a custom projection from a match directly into a list.
<pre>MATCH (person) RETURN person { .name, .age}</pre> Map projections may be easily constructed from nodes, relationships and other map values.

Labels
<code>CREATE (n:Person {name: \$value})</code> Create a node with label and property.
<code>MERGE (n:Person {name: \$value})</code> Matches or creates unique node(s) with the label and property.
<code>SET n:Spouse:Parent:Employee</code> Add label(s) to a node.
<code>MATCH (n:Person)</code> Matches nodes labeled <code>Person</code> .
<code>MATCH (n:Person) WHERE n.name = \$value</code> Matches nodes labeled <code>Person</code> with the given <code>name</code> .
<code>WHERE (n:Person)</code> Checks the existence of the label on the node.
<code>labels(n)</code> Labels of the node.
<code>REMOVE n:Person</code> Remove the label from the node.

Maps
<code>{name: 'Alice', age: 38, address: {city: 'London', residential: true}}</code> Literal maps are declared in curly braces much like property maps. Lists are supported.
<code>WITH {person: {name: 'Anne', age: 25}} AS p RETURN p.person.name</code> Access the property of a nested map.
<code>MERGE (p:Person {name: \$map.name}) ON CREATE SET p = \$map</code> Maps can be passed in as parameters and used either as a map or by accessing keys.
<code>MATCH (matchedNode:Person) RETURN matchedNode</code> Nodes and relationships are returned as maps of their data.
<code>map.name, map.age, map.children[0]</code> Map entries can be accessed by their keys. Invalid keys result in an error.

Predicates
<code>n.property <> \$value</code> Use comparison operators.
<code>exists(n.property)</code> Use functions.
<code>n.number >= 1 AND n.number <= 10</code> Use boolean operators to combine predicates.
<code>1 <= n.number <= 10</code> Use chained operators to combine predicates.
<code>n:Person</code> Check for node labels.
<code>variable IS NULL</code> Check if something is <code>null</code> .
<code>NOT exists(n.property) OR n.property = \$value</code> Either the property does not exist or the predicate is <code>true</code> .
<code>n.property = \$value</code> Non-existing property returns <code>null</code> , which is not equal to anything.
<code>n["property"] = \$value</code> Properties may also be accessed using a dynamically computed property name.
<code>n.property STARTS WITH 'Tob' OR n.property ENDS WITH 'n' OR n.property CONTAINS 'goodie'</code> String matching.
<code>n.property =~ 'Tob.*'</code> String regular expression matching.
<code>(n)-[:KNOWS]->(m)</code> Ensure the pattern has at least one match.
<code>NOT (n)-[:KNOWS]->(m)</code> Exclude matches to <code>(n)-[:KNOWS]->(m)</code> from the result.
<code>n.property IN [\$value1, \$value2]</code> Check if an element exists in a list.

List Predicates
<code>all(x IN coll WHERE exists(x.property))</code> Returns <code>true</code> if the predicate is <code>true</code> for all elements in the list.
<code>any(x IN coll WHERE exists(x.property))</code> Returns <code>true</code> if the predicate is <code>true</code> for at least one element in the list.
<code>none(x IN coll WHERE exists(x.property))</code> Returns <code>true</code> if the predicate is <code>false</code> for all elements in the list.
<code>single(x IN coll WHERE exists(x.property))</code> Returns <code>true</code> if the predicate is <code>true</code> for exactly one element in the list.

List Expressions
<code>size(\$list)</code> Number of elements in the list.
<code>head(\$list), last(\$list), tail(\$list)</code> <code>head()</code> returns the first, <code>last()</code> the last element of the list. <code>tail()</code> returns all but the first element. All return <code>null</code> for an empty list.
<code>[x IN list WHERE x.prop <> \$value x.prop]</code> Combination of filter and extract in a concise notation.
<code>extract(x IN list x.prop)</code> A list of the value of the expression for each element in the original list.
<code>filter(x IN list WHERE x.prop <> \$value)</code> A filtered list of the elements where the predicate is <code>true</code> .
<code>reduce(s = "", x IN list s + x.prop)</code> Evaluate expression for each element in the list, accumulate the results.

CASE
<code>CASE n.eyes WHEN 'blue' THEN 1 WHEN 'brown' THEN 2 ELSE 3 END</code> Return <code>THEN</code> value from the matching <code>WHEN</code> value. The <code>ELSE</code> value is optional, and substituted for <code>null</code> if missing.
<code>CASE WHEN n.eyes = 'blue' THEN 1 WHEN n.age < 40 THEN 2 ELSE 3 END</code> Return <code>THEN</code> value from the first <code>WHEN</code> predicate evaluating to <code>true</code> . Predicates are evaluated in order.

Functions
<code>coalesce(n.property, \$defaultValue)</code> The first non- <code>null</code> expression.
<code>timestamp()</code> Milliseconds since midnight, January 1, 1970 UTC.
<code>id(nodeOrRelationship)</code> The internal id of the relationship or node.
<code>toInteger(\$expr)</code> Converts the given input into an integer if possible; otherwise it returns <code>null</code> .
<code>toFloat(\$expr)</code> Converts the given input into a floating point number if possible; otherwise it returns <code>null</code> .
<code>toBoolean(\$expr)</code> Converts the given input into a boolean if possible; otherwise it returns <code>null</code> .
<code>keys(\$expr)</code> Returns a list of string representations for the property names of a node, relationship, or map.
<code>properties({expr})</code> Returns a map containing all the properties of a node or relationship.

Path Functions
<code>length(path)</code> The number of relationships in the path.
<code>nodes(path)</code> The nodes in the path as a list.
<code>relationships(path)</code> The relationships in the path as a list.
<code>extract(x IN nodes(path) x.prop)</code> Extract properties from the nodes in a path.

Spatial Functions
<code>point({x: {x}, y: {y}})</code> Returns a point in a 2D coordinate system.
<code>distance(point({x: {x1}, y: {y1}}), point({x: {x2}, y: {y2}}))</code> Returns a floating point number representing the geodesic distance between two points.

Mathematical Functions
<code>abs(\$expr)</code> The absolute value.
<code>rand()</code> Returns a random number in the range from 0 (inclusive) to 1 (exclusive), [0,1). Returns a new value for each call. Also useful for selecting a subset or random ordering.
<code>round(\$expr)</code> Round to the nearest integer; <code>ceil()</code> and <code>floor()</code> find the next integer up or down.
<code>sqrt(\$expr)</code> The square root.
<code>sign(\$expr)</code> 0 if zero, -1 if negative, 1 if positive.
<code>sin(\$expr)</code> Trigonometric functions also include <code>cos()</code> , <code>tan()</code> , <code>cot()</code> , <code>asin()</code> , <code>acos()</code> , <code>atan()</code> , <code>atan2()</code> , and <code>haversin()</code> . All arguments for the trigonometric functions should be in radians, if not otherwise specified.
<code>degrees(\$expr), radians(\$expr), pi()</code> Converts radians into degrees; use <code>radians()</code> for the reverse, and <code>pi()</code> for π .
<code>log10(\$expr), log(\$expr), exp(\$expr), e()</code> Logarithm base 10, natural logarithm, <i>e</i> to the power of the parameter, and the value of <i>e</i> .

String Functions
<code>toString(\$expression)</code> String representation of the expression.
<code>replace(\$original, \$search, \$replacement)</code> Replace all occurrences of <code>search</code> with <code>replacement</code> . All arguments must be expressions.
<code>substring(\$original, \$begin, \$subLength)</code> Get part of a string. The <code>subLength</code> argument is optional.
<code>left(\$original, \$subLength), right(\$original, \$subLength)</code> The first part of a string. The last part of the string.
<code>trim(\$original), lTrim(\$original), rTrim(\$original)</code> Trim all whitespace, or on the left or right side.
<code>toUpper(\$original), toLower(\$original)</code> UPPERCASE and lowercase.
<code>split(\$original, \$delimiter)</code> Split a string into a list of strings.
<code>reverse(\$original)</code> Reverse a string.
<code>size(\$string)</code> Calculate the number of characters in the string.

Relationship Functions
<code>type(a_relationship)</code> String representation of the relationship type.
<code>startNode(a_relationship)</code> Start node of the relationship.
<code>endNode(a_relationship)</code> End node of the relationship.
<code>id(a_relationship)</code> The internal id of the relationship.

Aggregating Functions
<code>count(*)</code> The number of matching rows.
<code>count(variable)</code> The number of non- <code>null</code> values.
<code>count(DISTINCT variable)</code> All aggregating functions also take the <code>DISTINCT</code> operator, which removes duplicates from the values.
<code>collect(n.property)</code> List from the values, ignores <code>null</code> .
<code>sum(n.property)</code> Sum numerical values. Similar functions are <code>avg()</code> , <code>min()</code> , <code>max()</code> .
<code>percentileDisc(n.property, \$percentile)</code> Discrete percentile. Continuous percentile is <code>percentileCont()</code> . The <code>percentile</code> argument is from 0.0 to 1.0.
<code>stDev(n.property)</code> Standard deviation for a sample of a population. For an entire population use <code>stDevP()</code> .

INDEX
<code>CREATE INDEX ON :Person(name)</code> Create an index on the label <code>Person</code> and property <code>name</code> .
<code>MATCH (n:Person) WHERE n.name = \$value</code> An index can be automatically used for the equality comparison. Note that for example <code>toLower(n.name) = \$value</code> will not use an index.
<code>MATCH (n:Person) WHERE n.name IN [\$value]</code> An index can automatically be used for the <code>IN</code> list checks.
<code>MATCH (n:Person) USING INDEX n:Person(name) WHERE n.name = \$value</code> Index usage can be enforced when Cypher uses a suboptimal index, or more than one index should be used.
<code>DROP INDEX ON :Person(name)</code> Drop the index on the label <code>Person</code> and property <code>name</code> .

CONSTRAINT
<code>CREATE CONSTRAINT ON (p:Person) ASSERT p.name IS UNIQUE</code> Create a unique property constraint on the label <code>Person</code> and property <code>name</code> . If any other node with that label is updated or created with a <code>name</code> that already exists, the write operation will fail. This constraint will create an accompanying index.
<code>DROP CONSTRAINT ON (p:Person) ASSERT p.name IS UNIQUE</code> Drop the unique constraint and index on the label <code>Person</code> and property <code>name</code> .
<code>CREATE CONSTRAINT ON (p:Person) ASSERT exists(p.name)</code> Create a node property existence constraint on the label <code>Person</code> and property <code>name</code> . If a node with that label is created without a <code>name</code> , or if the <code>name</code> property is removed from an existing node with the <code>Person</code> label, the write operation will fail.
<code>DROP CONSTRAINT ON (p:Person) ASSERT exists(p.name)</code> Drop the node property existence constraint on the label <code>Person</code> and property <code>name</code> .
<code>CREATE CONSTRAINT ON ()-[l:LIKED]-() ASSERT exists(l.when)</code> Create a relationship property existence constraint on the type <code>LIKED</code> and property <code>when</code> . If a relationship with that type is created without a <code>when</code> , or if the <code>when</code> property is removed from an existing relationship with the <code>LIKED</code> type, the write operation will fail.
<code>DROP CONSTRAINT ON ()-[l:LIKED]-() ASSERT exists(l.when)</code> Drop the relationship property existence constraint on the type <code>LIKED</code> and property <code>when</code> .

Performance
<ul style="list-style-type: none">Use parameters instead of literals when possible. This allows Cypher to re-use your queries instead of having to parse and build new execution plans.Always set an upper limit for your variable length patterns. It's easy to have a query go wild and touch all nodes in a graph by mistake.Return only the data you need. Avoid returning whole nodes and relationships — instead, pick the data you need and return only that.Use <code>PROFILE / EXPLAIN</code> to analyze the performance of your queries. See Query Tuning for more information on these and other topics, such as planner hints.
